

Exercises " Advanced materials B"

#4

Exercise 4: Orientation polarization

Fig. 1: (a) H₂O molecule, (b) Schematic snapshot of the distribution of water molecules in a liquid.

The permanent dipole moment of a single water molecule is $p = 6 \cdot 10^{-28}$ Ccm and the molar weight of water is $M = 18$ g/mol. Without an external electrical field all dipoles are oriented randomly.

- Draw the direction of the dipole moment of each H₂O in **Fig. 1b**.
- What is the sum of the dipole moments in this case?
- How may the dipole distribution look at the next snapshot a few ms later?
- Calculate the molecular density of H₂O!
- Calculate the polarization for the case that all dipoles are aligned along the field!
- Describe qualitatively how the dipole configuration changes if a field is applied!

The dielectric constant of water is $\epsilon_r = 78.5$.

- If you use the macroscopic polarization formula $P = \chi \cdot \epsilon_0 \cdot E$, what polarization results at $E = 100000$ V/cm? What does this mean physically, or better, how could the dipoles be distributed on a snapshot like in **Fig. 1b**?
- Draw and discuss the polarization as a function of the external field strength. Use the three polarization values you have (no field; $E = 100000$ V/cm; all dipoles aligned).
- Explain why SiCl₄ only has $\epsilon_r = 2.4$, while CHN has $\epsilon_r = 114$ (all liq. @ 20 °C)!
- What happens when the liquid freezes?
