## **Overview of Heating Materials**

- The diagram shows the temperature range and the resistivity of typical materials for heating elements.
  - On not forget that humble **1500** °C (roughly the melting point of iron) means that it is *really* hot! Mankind had to invent pretty tricky crafts for about **2000** years because <u>nobody could reach the melting point of iron</u>.
  - Beyond 2000 °C there are not many usable materials left. Essentially you are stuck with graphite (not in the figure).
