## 5.4 Summary

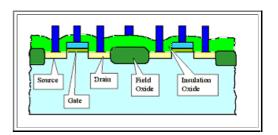

## 5.4.1 Summary to 5: Integrated Circuits - Process Integration

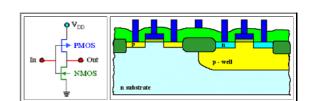

- Integration means:
  - 1. Produce a large number (up to 1.000.000.000) of transistors (bipolar or MOS) and other electronic elements on a cm<sup>2</sup> of Si
  - 2. Keep thoses elements electrically insulated from each other.
  - 3. Connect those elements in a meaningful way to produce a system / product.
- An integrated bipolar transistor does not resemble the textbook picture at all, but looks far more complicated ⇒.
  - This is due to the insulation requirements, the process requirements, and the need to interconnect as efficiently as possible.
  - The epitaxial layer cuts down on the number of critical diffusions, makes insulation easier, and allows a "buried contact" structure.
- Connecting transistor / elements is complicated; it has to be done on several levels
  - Materials used are AI ("old"), Cu ("new"), W, (highly doped) poly-Si as well as various silicides.
  - Essential properties are the conductivity σ of the conductor, the dielectric constant ∈<sub>r</sub> of the intermetal dielectric, and the resulting time constant τ = σ ⋅ ∈<sub>r</sub> that defines the maximum signal transmision frequency through the conducting line.
- Integrating **MOS** transistors requires special measures for insulation (e.g. a field oxide) and for gate oxide production
  - Since a MOS transistor contains intrinsically a capacitor (the gate "stack"), the technology can be used to produce capacitors, too.
- CMOS allows to reduce power consumption dramatically.
  - The process, however, is more complex: Wells with different doping type need to be made.

It ain't easy!

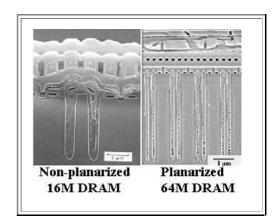

- Using the third dimension (depth / height) might become necessary for integrating "large" structures into a small projected are (example: trench capacitor in **DRAMs** ⇒).
  - Unwanted "topology", however, makes integration more difficult.
  - Planarized technologies are a must since about 1995! ⇒

It ain't neither easy nor cheap!
