FOBIC Process

- Consider making a contact hole through the CVD oxide that was deposited over the finished transistors.
 - Since the source/drain area are as small as possible, you have to make not only a small hole but you must align it precisely relative to the gate stack of the transistors.
 - Small misalignements would produce a short circuit between the gate electrode and the AI that will be put in the contact hole eventually.
 - Now cover the whole gate stack with Si₃N₄ that will resist whatever etching procedure you use to remove the oxide in the future contact hole. You gain a lot in your "process window" for the contact hole misalignements don't matter as much any more as shown below.

- That looks pretty good but there is a prize to pay:
 - First of all how do we make the nitride encapsulation? And don't forget; Si₃N₄ must never come in contact with Si you always need a thin layer of <u>buffer oxide</u> underneath (not shown in the picture). There is quite a bit of added process complexity!
 - The topography gets worse. The aspect ratio of the contact hole the relation between depth and diameter increases and with it the problems of filling it with AI.
 - Still, starting around 1987, FOBIC was used and helped to get the next generation onto the market.
- The picture below is a cross section through a **16 Mbit DRAM** memory cell <u>shown before</u>. It shows one of the contacts to a transistor (which is connected on the other side to a <u>trench capacitor</u>). The **FOBIC** structure has been outlined; it is clearly visible.
